ShimoPay

Payments during connectivity outages

Authorize locally. Settle in USDC when connectivity returns.

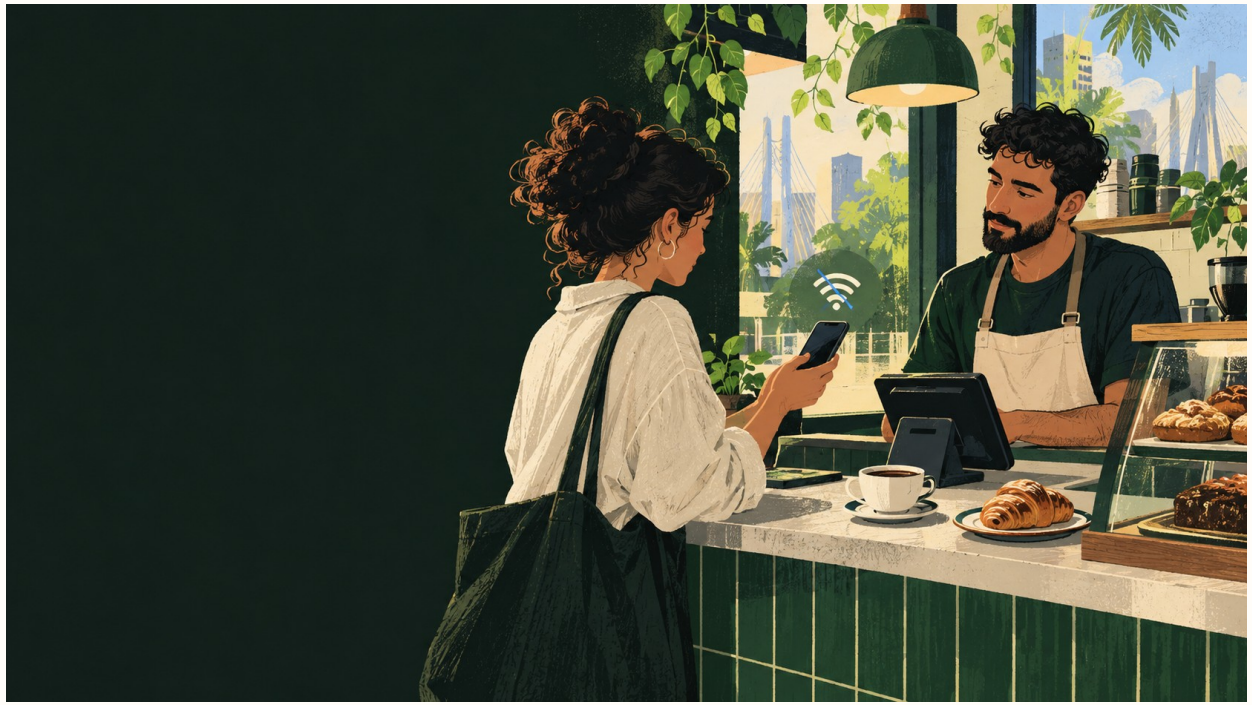

Diego Shimohama
São Paulo, Brazil

Solana Devnet prototype. English deck with original Portuguese product screens.

The checkout problem

The customer is ready.
The connection fails.

A merchant must wait, ask for another payment method or accept uncertainty.

Need to validate: how often outages affect checkout and which merchants lose sales.

The merchant’s reason to pay

Checkout continuity

Accept a locally verifiable payment intent.
See what remains pending.
Reconcile after connectivity returns.

8 recovered sales

could cover BRL 79/month

Illustration: BRL 25 ticket
and 40% contribution margin.
BRL 10 contribution per sale.

Illustrative economics before fees, support costs and failed-settlement losses.

Brazil’s small-ticket payment market

24 million

active small businesses in Brazil

76%

of Pix transactions between individuals and businesses were up to BRL 60 in 2025

Sources: Sebrae, June 2026. Banco Central do Brasil, Pix report 2023–2025, p.14.

The first addressable customer

Initial segment	Cafés and independent food vendors in São Paulo. Small purchases where waiting can disrupt checkout.
Qualification	Recurring connectivity interruptions, compatible phones and willingness to accept pending settlement.
First scale target	100 paying locations after pilot validation. The reachable merchant count still needs research.

Expansion hypothesis: merchant software distribution, then other Brazilian cities.

How ShimoPay addresses the problem

01 Prepare online

The customer reserves a spending allowance in escrow.
The merchant caches the session policy.

02 Authorize offline

The customer signs locally and shares a QR or envelope.
The merchant verifies and records pending settlement.

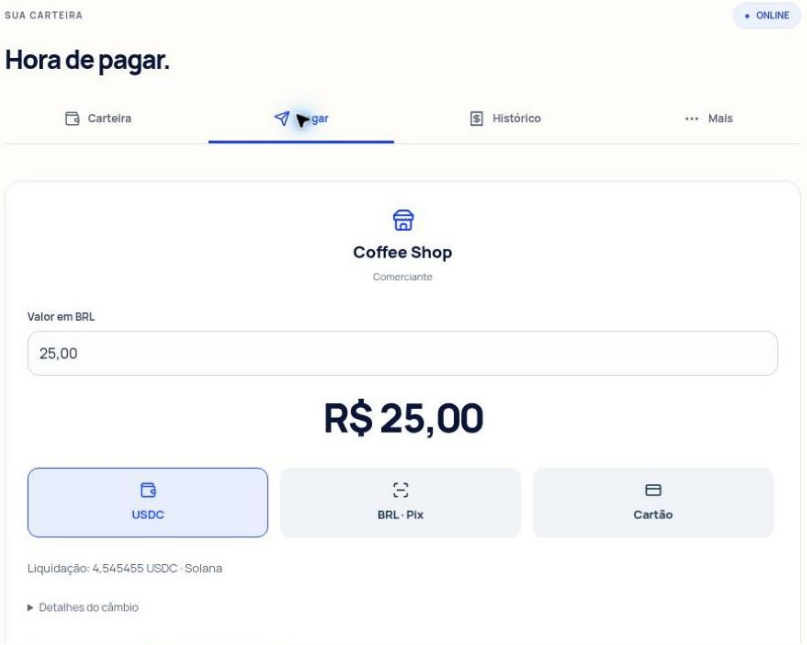

03 Settle online

Either party reconnects to submit the payment.
Solana transfers USDC and provides an on-chain receipt.

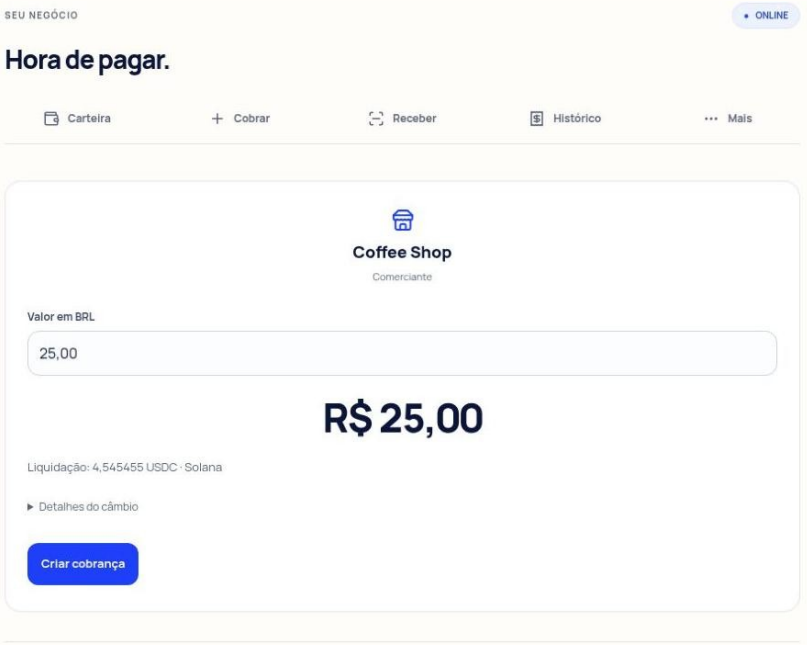

Pending acceptance carries risk until settlement. Current implementation uses test USDC.

The customer and merchant product

Customer reviews the purchase

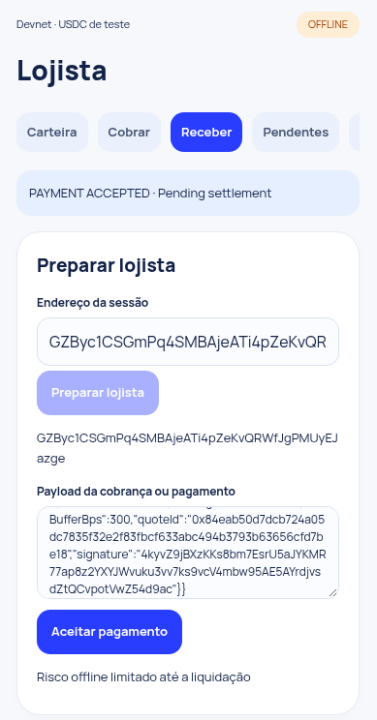

Merchant prepares a charge

Current UI, Oct 14. USDC on Devnet. Pix/card online sandbox. Fiat conversion/payout simulated.

Offline acceptance and pending settlement

Local verification without network calls

The merchant verifies locally.

Only the merchant reconnects in the recorded test.

Acceptance and settlement have separate visible states.

Recorded developer test, Oct 12, earlier UI. Merchant risk remains until final settlement.

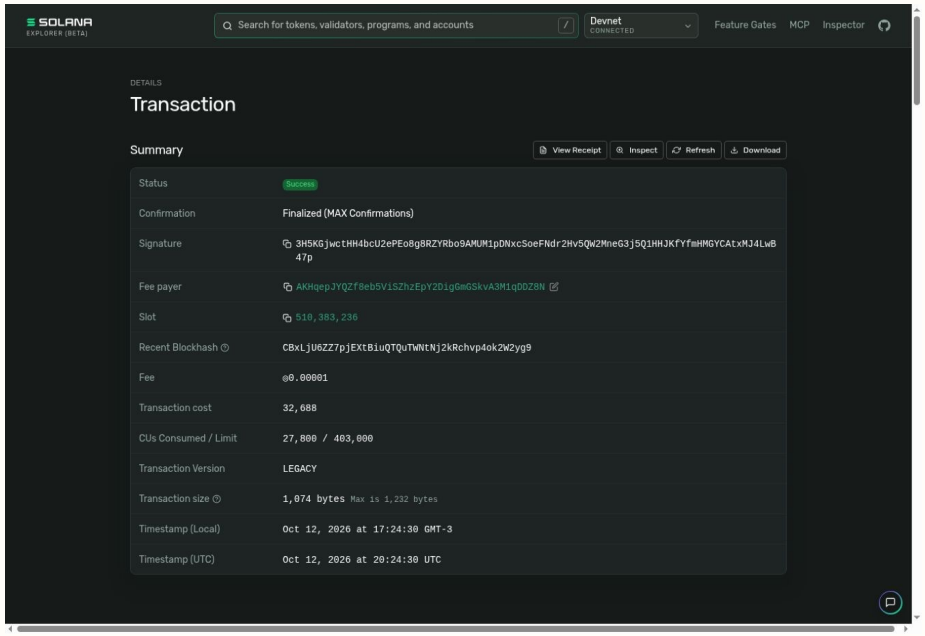

Technical progress with verifiable evidence

2 payments

BRL 25 each
1 online, 1 authorized offline
4.545455 test USDC each

Developer tests.
No validated merchant pilot
or revenue yet.

Alternatives and ShimoPay’s positioning

Alternative	What it offers	ShimoPay’s proposed position
Cash	Checkout without connectivity	Digital record and later USDC settlement
Offline card systems	Deferred processing under provider rules	Phone-based intent with Solana escrow
Solana Pay	Standard QR / URL payment requests	Local intent verification, later settlement

Offline payments already exist. Superiority, adoption cost and loss rates require benchmarking.

How ShimoPay would make money

BRL 49–99

per merchant location / month

Proposed subscription for checkout continuity and payment reconciliation. Consumer access without a subscription.

Who pays

The merchant benefiting from payment continuity.

Later revenue options

Partner software licensing and service commissions, after adoption validation.

All pricing and future revenue options are hypotheses. Network/provider fees need separate design.

Subscription revenue scenarios

Paying locations	Monthly revenue	Annual recurring run rate
100	BRL 7,900	BRL 94,800
1,000	BRL 79,000	BRL 948,000
10,000	BRL 790,000	BRL 9,480,000

Profitability depends on support, security, provider fees and who bears failed offline settlement losses.

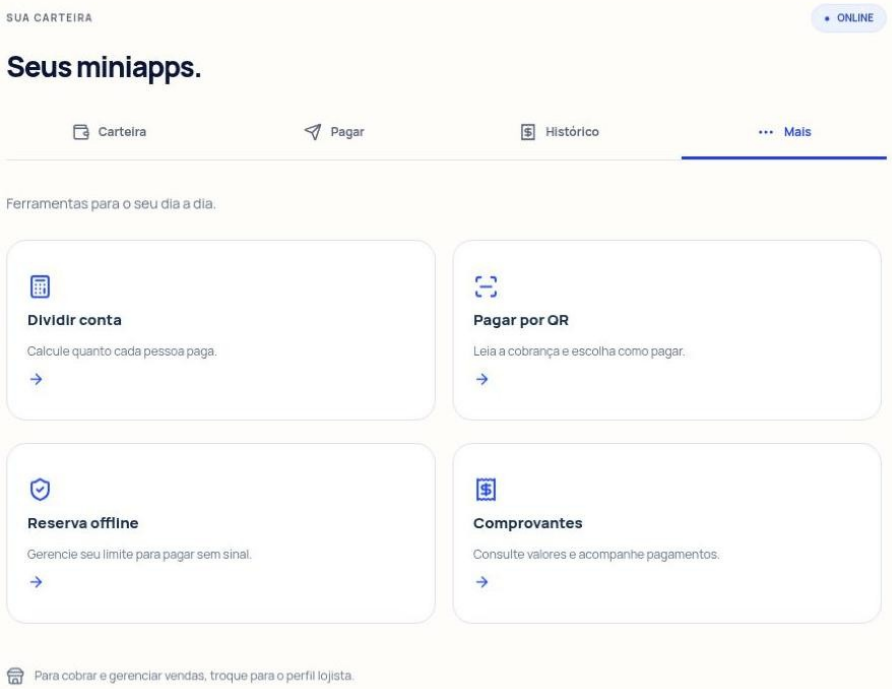

Illustrative scenarios at BRL 79/month. These are not forecasts or achieved revenue.

Go-to-market starts with merchant discovery

Discovery	Interview 8–12 São Paulo establishments. Record outage frequency, lost sales and current workarounds.
Design partners	Seek 2 merchants to test the workflow with test tokens. Measure repeat use and willingness to pay.
Distribution	Start with direct onboarding. Test merchant software partnerships after the pilot economics work.

Success criteria: repeat usage, reliable settlement and value above fees and acceptance losses.

A wallet with a path to everyday services

Today

Payment tools share one consumer experience.

After merchant adoption

Add services and partner integrations that increase useful wallet activity.

Current tools shown. Partner marketplace and commission revenue remain future hypotheses.

The path to a controlled commercial pilot

Wallet security	Individual ownership and transaction authentication. Protected device keys and tested recovery.
Acceptance policy	Define purchase/session limits and loss allocation. Conflicting intents can still fail at settlement.
Commercial readiness	Resolve compliance and fiat provider requirements. Run a controlled pilot before handling real funds.

Mainnet and production fiat depend on these gates. Escrow does not guarantee every accepted payment.

Founder fit and the next milestone

Diego Shimohama

25+ years in IT, security, identity and infrastructure.
Founder of Naapi and Hack-Cancer. Builder of BioFlow.

Naapi claims assessment: 20 days to 3 minutes.
Experience with fraud identification and instant payments.

Seeking merchant design partners and technical mentorship
to validate a controlled pilot and a full-time transition.
